

# CE1107/CZ1107: DATA STRUCTURES AND ALGORITHMS

**Binary Trees** 

**College of Engineering** 

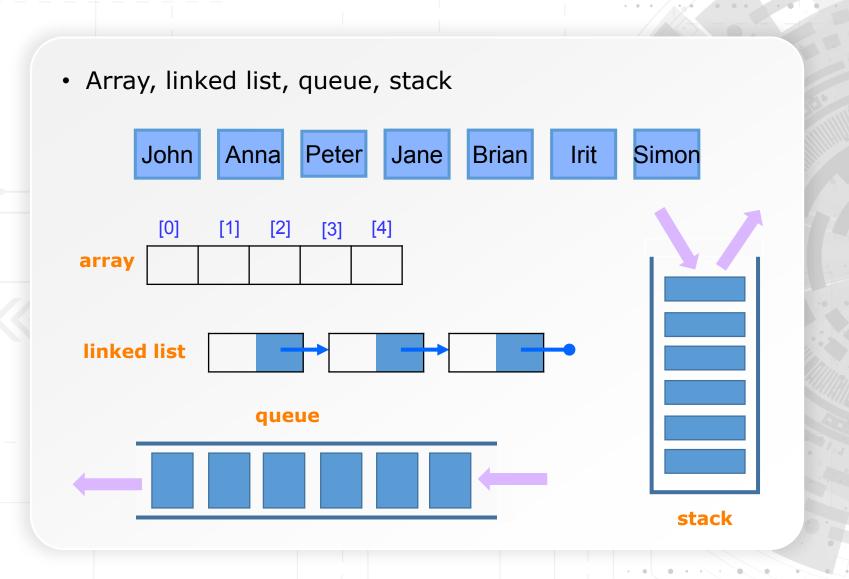

School of Computer Science and Engineering

#### **OUTLINE**

#### Non-linear data structures

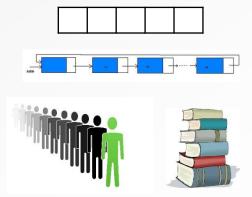

- Tree data structure
  - Binary trees
- · Implement binary tree nodes in C
- Binary Tree Traversal
- Tree traversal order
  - Pre-order
  - In-order
  - Post-order
- Application examples
  - Count nodes in a binary tree
  - Find grandchild nodes
  - Calculate height of every node
- Level-by-level traversal
- Preorder traversal with a stack

# **LINEAR DATA STRUCTURE**

# **DATA STRUCTURES SO FAR...**

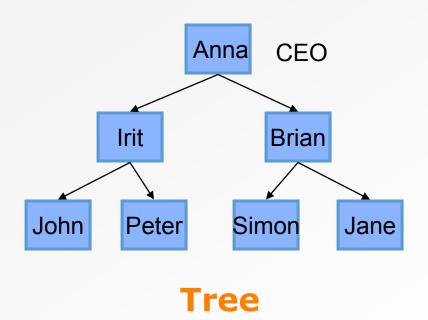

- Linear
  - Items all arranged one after another
  - Random access
    - Arrays
  - Sequential access
    - Linked list
  - Limited-access sequential
    - Stacks
    - Queues

- Used them to store lists of numbers, lists of people, lists of moves, etc
  - Linear data

# **NON-LINEAR DATA STRUCTURE**

Suppose you have a set of names

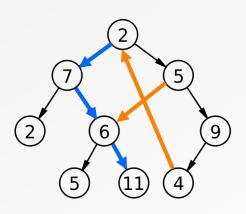

Company organization

Not good to use linear data structure to store <u>hierarchical relationships</u>

### TREE DATA STRUCTURE

- Still using nodes + links representation
- New idea:
  - Each node can have links to more than one other node
  - No loop ( With Gop, becomes class)

#### **Observe that:**

 If we follow one path of a tree, we get a linked list

#### **OUTLINE**

- Non-linear data structures
- Tree data structure
  - Binary trees
- · Implement binary tree nodes in C
- Binary Tree Traversal
- Tree traversal order
  - Pre-order
  - In-order
  - Post-order
- Application examples
  - Count nodes in a binary tree
  - Find grandchild nodes
  - Calculate height of every node
- Level-by-level traversal
- Preorder traversal with a stack

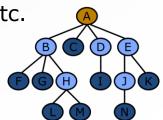

### TREE DATA STRUCTURE

- A tree is composed of nodes
- Each node contains a value
- Types of nodes
  - Root: only one in a tree, has no parent.
  - Internal (non-leaf):
     Nodes with children are called internal nodes
  - Leaf:nodes without children are calledleaves

#### **WHY TREES?**

- Model layouts with hierarchical relationships between items
  - Chain of command in the army
  - Personnel structure in a company
  - (Binary tree structure is limited because each node can have at most two children)
- Tree structures also allow us to
  - Some problems require a tree structure: some games, most optimization problems, etc.
  - Allow us to do the following very quickly: (we'll see that in the following lectures)
    - Search for a node with a given value
    - Add a given value to a list
    - Delete a given value from a list

### TREE DATA STRUCTURE

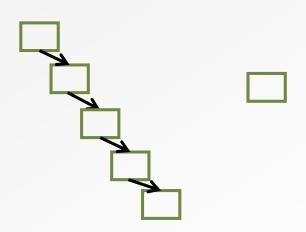

- Tree data structure looks like... a tree:
  - Only one root node (no nodes points to it)
  - Each node branches out to some number of nodes
  - Each node has only one "parent" node the node pointing to it (except the root node)

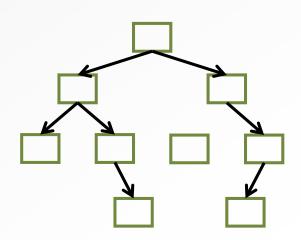

- General tree
  - Each node can have links to any number of other nodes
- Binary tree (we'll work with this in our course)
  - Each node can have links to at most two other nodes

# **POSSIBLE TREE CONFIGURATIONS**

- We'll see later why not all trees configurations are desirable/useful
- Has to do with balance of a tree

#### **OUTLINE**

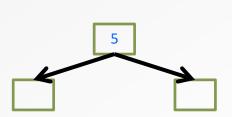

- Non-linear data structures
- Tree data structure
  - Binary trees
- Implement binary tree nodes in C
- Binary Tree Traversal
- Tree traversal order
  - Pre-order
  - In-order
  - Post-order
- Application examples
  - Count nodes in a binary tree
  - Find grandchild nodes
  - Calculate height of every node
- Level-by-level traversal
- Preorder traversal with a stack

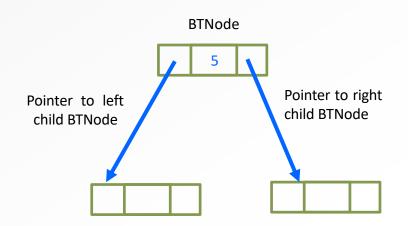

### **IMPLEMENTATION**

- Recall implementation of LinkedList
  - Node has link to **at most one** other node
  - Defined a ListNode with one next pointer and a data item

```
typedef struct _listnode{
   int item;
   struct _listnode *next;
}ListNode;
```

- BinaryTree
  - Node has link to at most <u>TWO</u> other nodes
  - Define a BTNode with
    - Two pointers
    - A data item

### **BTNode**

- Start with a simple BTNode that stores an integer
  - The type of item can be character, string, or structure, etc.

```
typedef struct _listnode{
    int item;
    struct _listnode *next;
}ListNode;

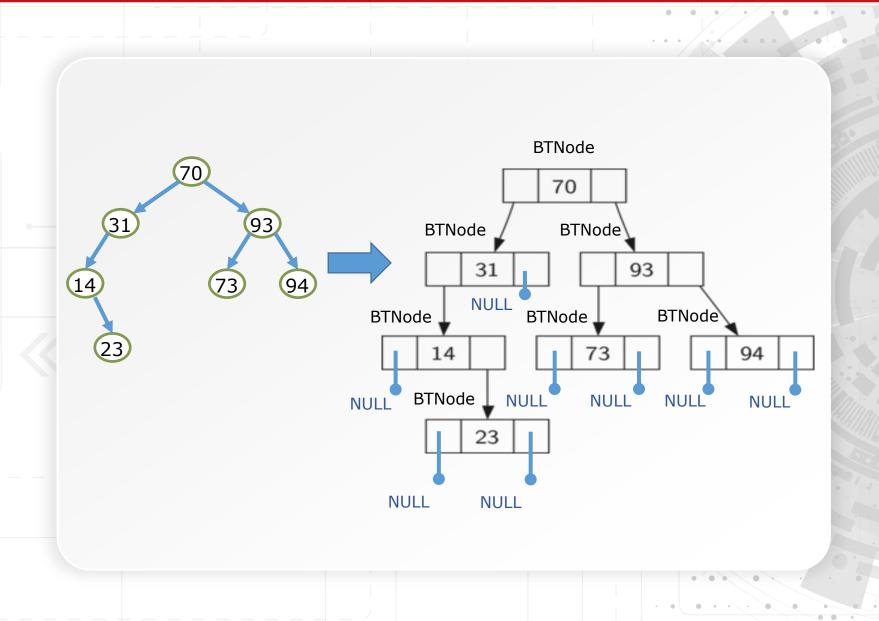

struct _btnode *left;
    struct _btnode *right;

BTNode

Pointer to left
child BTNode

Pointer to right
child BTNode
```

# **EXAMPLE BINARY TREE**

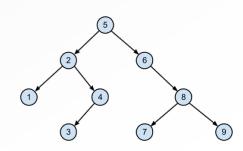

#### **OUTLINE**

- Non-linear data structures
- Tree data structure
  - Binary trees
- Implement binary tree nodes in C
- Binary Tree Traversal
- Tree traversal order
  - Pre-order
  - In-order
  - Post-order
- Application examples
  - Count nodes in a binary tree
  - Find grandchild nodes
  - Calculate height of every node
- Level-by-level traversal
- Preorder traversal with a stack

#### TREE TRAVERSAL

- Given a linear data structure and a particular item, very obvious what the "next" item is
  - Each node has an obvious "previous" and "next" node
- Trees are non-linear structures
  - How to extract data from a binary tree?
  - What is the traversal sequence?left/left/left, then left/left/right, then...?
- Need a systematic way to visit every node in the tree
  - Clearly defined steps
  - No repeated visits to nodes

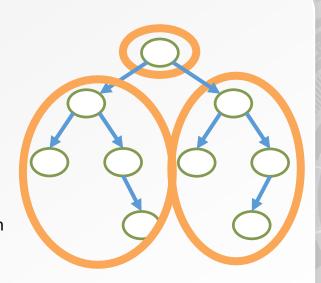

### TREE TRAVERSAL

- Why is this important?
  - Tree traversal is foundation for many functions
- Very common function template:

#### Traverse tree

• At each node, perform some operation

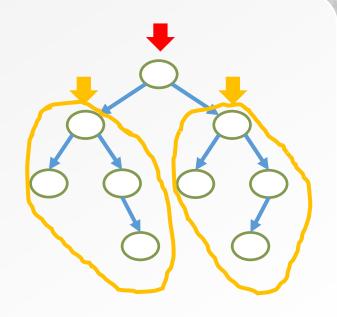

- Example task: count # of nodes in a tree
  - At every node N, size of that subtree
  - = size of N's left subtree
    - + size of N's right subtree
    - + N itself

#### TREE TRAVERSAL

- Tree traversal is recursive
  - Recursion: is the process of repeating items in a <u>self-similar</u> way; divide a problem into several similar sub-problems.
  - At each node
    - Visit the node and both children
- Initial case + repeating case
  - (Visit root) + (visit children)
- When combined, guarantees that all nodes will be visited once and only once

# TREE TRAVERSAL PROCESS

```
TreeTraversal(Node N):
    Visit N;
    If (N has left child)
        TreeTraversal(LeftChild);
    If (N has right child)
        TreeTraversal(RightChild);
    Return; // return to parent
```

### TREE TRAVERSAL TEMPLATE #1

### <u>Pseudocode</u>

```
TreeTraversal(Node N):
    Visit N;
    If (N has left child)
        TreeTraversal(LeftChild);
    If (N has right child)
        TreeTraversal(RightChild);
    Return; // return to parent
```

In main(), call TreeTraversal(root)

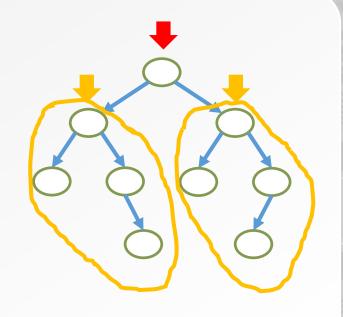

### TREE TRAVERSAL TEMPLATE #2

#### Current function:

 Need to check for existence of left and right children before following them

- Always follow links to children
- Then check if the link is NULL
- In other words, not actually pointing at a BTNode

# TREE TRAVERSAL TEMPLATE #2

### **Pseudocode**

```
TreeTraversal2(Node N):

    If N==NULL return;

    Visit N;

    TreeTraversal2(LeftChild);

    TreeTraversal2(RightChild);

    Return; // return to parent
```

In main(), call TreeTraversal2(root)

# TreeTraversal2() IMPLEMENTATION

```
Void TreeTraversal2(BTNode *cur) {
    If (cur == NULL) return;
    PrintNode(cur); // visit cur
    TreeTraversal2(cur->left);
    TreeTraversal2(cur->right);
}
```

# TREETRAVERSAL() FEATURES

#### Recursive

TreeTraversal() is called <u>from within</u>
 <u>its own body</u>

initial call TreeTraversal(root)

### Depth-first

- The traversal goes as <u>deep</u> as possible before backtracking and going sideways
- Not level-by-level! (that is called breadth-first)

# OUTLINE

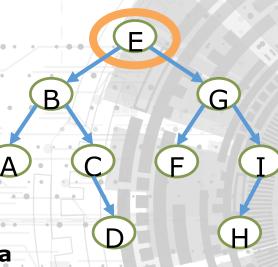

- Non-linear data structures
- Tree data structure
  - Binary trees
- Implement binary tree nodes in C
- Binary Tree Traversal
- Tree traversal order
  - Pre-order
  - In-order
  - Post-order
- Application examples
  - Count nodes in a binary tree
  - Find grandchild nodes
  - Calculate height of every node
- Level-by-level traversal
- Preorder traversal with a stack

# THREE "STANDARD" WAYS TO TRAVERSAL

- Pre-order
  - Process the current node's data
  - Visit the left child subtree
  - Visit the right child subtree
- In-order
- Post-order

### THREE "STANDARD" WAYS TO TRAVERSAL

- Pre-order
  - Process the current node's data
  - Visit the left child subtree
  - Visit the right child subtree
- In-order
  - Visit the left child subtree
  - Process the current node's data
  - Visit the right child subtree
- Post-order

### THREE "STANDARD" WAYS TO TRAVERSAL

#### Pre-order

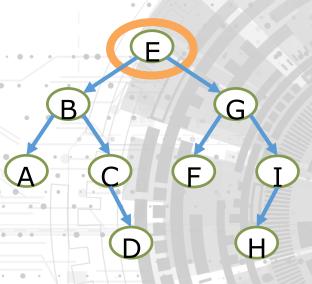

- Process the current node's data
- Visit the left child subtree
- Visit the right child subtree

#### In-order

- Visit the left child subtree
- Process the current node's data
- Visit the right child subtree

#### Post-order

- Visit the left child subtree
- Visit the right child subtree
- Process the current node's data

#### TREE TRAVERSAL - PRINT

- Recall the TreeTraversal() template (TT) Pre-order :
  - Simple task at each node: print out data in that node

```
void TreeTraversal(BTNode *cur) {
   if (cur == NULL)
     return;
```

// Do something with the current node's data

```
TreeTraversal(cur->left); //Visit the left child node
TreeTraversal(cur->right);//Visit the right child node
```

#### **TREE TRAVERSAL - PRINT**

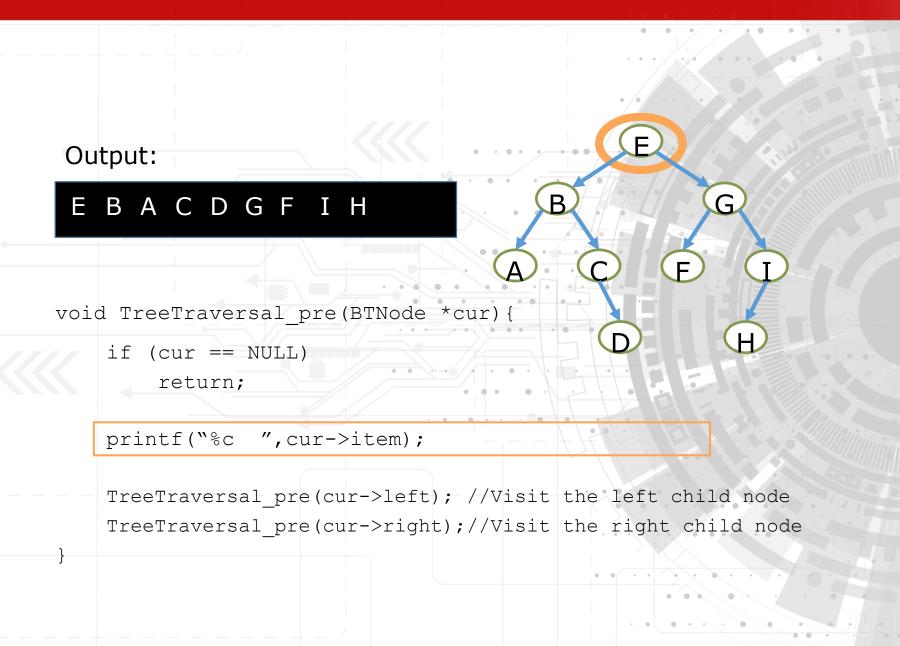

- Recall the TreeTraversal() template (TT) Pre-order :
  - Simple task at each node: print out data in that node

```
void TreeTraversal(BTNode *cur) {
   if (cur == NULL)
      return;

   printf("%c",cur->item);

   TreeTraversal(cur->left); //Visit the left child node
   TreeTraversal(cur->right);//Visit the right child node
}
```

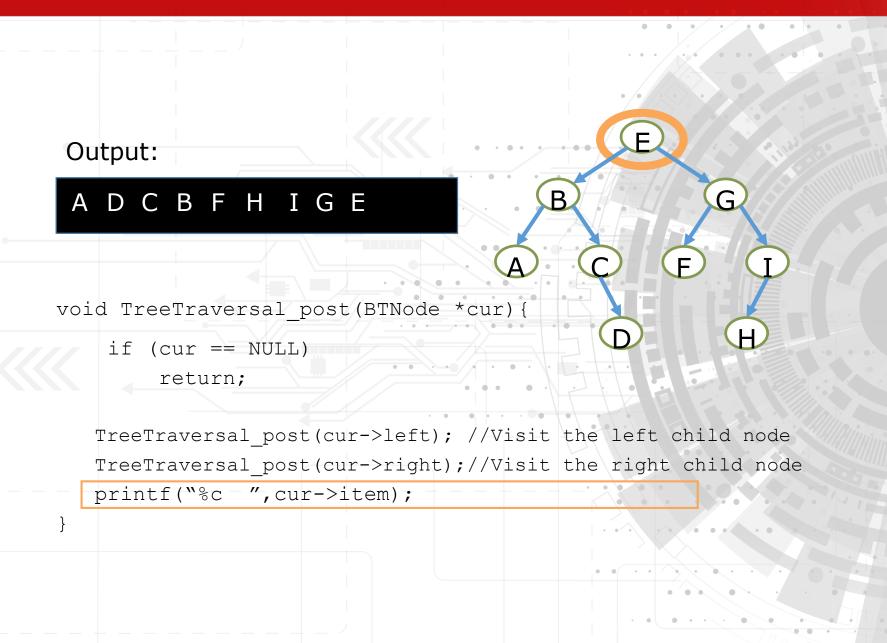

### TREE TRAVERSAL PRE-ORDER: PRINT

### TREE TRAVERSAL IN-ORDER: PRINT

### TREE TRAVERSAL POST-ORDER: PRINT

# PRE-ORDER, IN-ORDER AND POST-ORDER

Pre-Order Traversal BACDGFIH **In-Order Traversal** BCDEFGHI Post-Order Traversal BFHIGE

#### **OUTLINE**

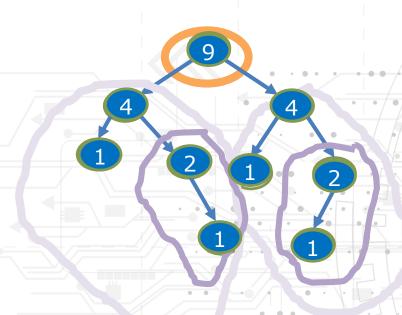

- Non-linear data structures
- Tree data structure
  - Binary trees
- Implement binary tree nodes in C
- Binary Tree Traversal
- Tree traversal order
  - Pre-order
  - In-order
  - Post-order
- Application examples
  - Count nodes in a binary tree
  - Find grandchild nodes
  - Calculate height of every node
- Level-by-level traversal
- Preorder traversal with a stack

### **COUNT NODES IN A BINARY TREE**

- Recursive definition:
  - Number of nodes in a tree
    - = 1
      - + number of nodes in left subtree
      - + number of nodes in right subtree
- Each node returns the number of nodes in its subtree

### **COUNT NODES IN A BINARY TREE**

- · Each node returns the number of nodes in its own subtree
- Leaf nodes return 1
   Information **propagates upwards** as TreeTraversal returns from visiting leaf nodes
- Which is the first/last count to be returned?

- Return the size of your subtree to your parent node
- Leaf nodes must return 1 to parent node
- Root node returns size of entire tree

```
void TreeTraversal(BTNode *cur) {
    if (cur == NULL)
        return;

    //may do something with cur;

    TreeTraversal(cur->left);

    TreeTraversal(cur->right);

    //may do something with cur;
}
```

- Return the size of your subtree to your parent node
- Leaf nodes must return 1 to parent node
- Root node returns size of entire tree

```
int countNode(BTNode *cur) {
   if (cur == NULL)
      return ???;

   countNode(cur->left);
   countNode(cur->right);
   ??? //sum and get total;
}
```

- Leaf nodes must return 1
  - "Null" nodes should return 0
- Leaf node returns 1 + 0 + 0

```
int countNode(BTNode *cur) {
    if (cur == NULL)
        return 0;

l = countNode(cur->left);
r = countNode(cur->right);
    return l+r+1;
}
```

- Leaf nodes must return 1
  - "Null" nodes should return 0
- Leaf node returns 1 + 0 + 0

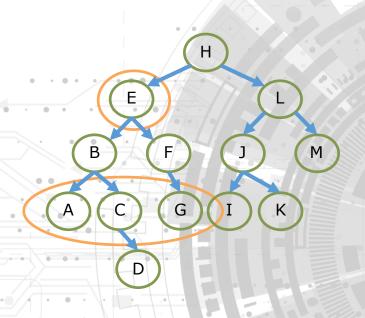

```
int countNode(BTNode *cur) {
   if (cur == NULL)
      return 0;

   return (countNode(cur->left)
      + countNode(cur->right)
      + 1);
}
```

#### **OUTLINE**

- Non-linear data structures
- Tree data structure
  - Binary trees
- Implement binary tree nodes in C
- Binary Tree Traversal
- Tree traversal order
  - Pre-order
  - In-order
  - Post-order
- Application examples
  - Count nodes in a binary tree
  - Find grandchild nodes
  - Calculate height of every node
- Level-by-level traversal
- Preorder traversal with a stack

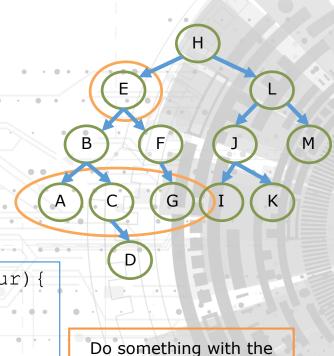

- Given a node X, find all the nodes that are X's grandchildren
- Given node E, we should return grandchild nodes A, C, and G
- What if we want to find klevel grandchildren?
  - Need a way to keep track of how many levels down we've gone

X->left->left X->left->right X->right->left X->right->right

2-level grandchildren

- We want to go down k "levels"
- Use a counter to track how far down we've gone
- At each TreeTraversal(child), increment counter

```
void TreeTraversal(BTNode *cur) {
   if (cur == NULL)
      return;
      Do something with the current node's data

// check counter
      Visit the left child node

TreeTraversal(cur->left);
      TreeTraversal(cur->right);
      Visit the right child node
}
```

```
H
void main() { ...
    if (X = null) return;
    findgrandchildren(X,0);
                                                                  M
   void findgrandchildren (
                 BTNode *cur, int c)
       if (cur == NULL) return;
2.
3.
       if (c == k) {
           printf("%d ", cur->item);
4.
5.
           return;
6.
        if (c < k) {
7.
           findgrandchildren(cur->left, c+1);
8.
           findgrandchildren(cur->right, c+1);
9.
10.}
```

```
void main() { ...
                                                         \mathbf{H}
    if (X = null) return;
    findgrandchildren(X,0);
                                                                    M
void findgrandchildren(
              BTNode *cur, int c) {
    if (cur == NULL) return;
                                                  if k=2, we call
    if (c == k) {
                                                  findgrandchildren(H,0),
       printf("%d ", cur->item);
                                                  what is the output?
       return;
                                                  How about k=3?
    if (c < k) {
                                                  How about
       findgrandchildren(cur->left, c+1);
                                                  findgrandchildren(H,1)?
       findgrandchildren(cur->right, c+1); }
```

#### **OUTLINE**

- Non-linear data structures
- Tree data structure
  - Binary trees
- Implement binary tree nodes in C
- Binary Tree Traversal
- Tree traversal order
  - Pre-order
  - In-order
  - Post-order
- Application examples
  - Count nodes in a binary tree
  - Find grandchild nodes
  - Calculate height of every node
- Level-by-level traversal
- Preorder traversal with a stack

 Height of a node = number of links from that node to the deepest leaf node

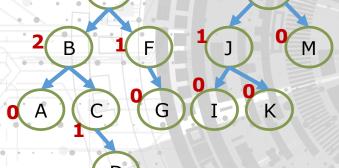

- What is the height of node D, C, H?
- We found:
  - leaf.height= 0
  - Non-leaf node X

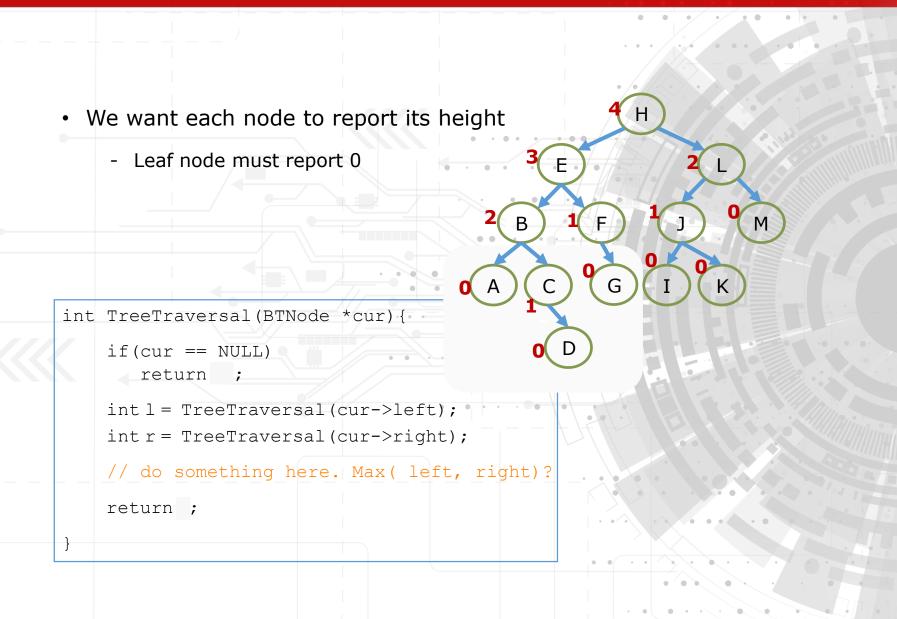

X.height=max(X.left.height, X.right.height)+1

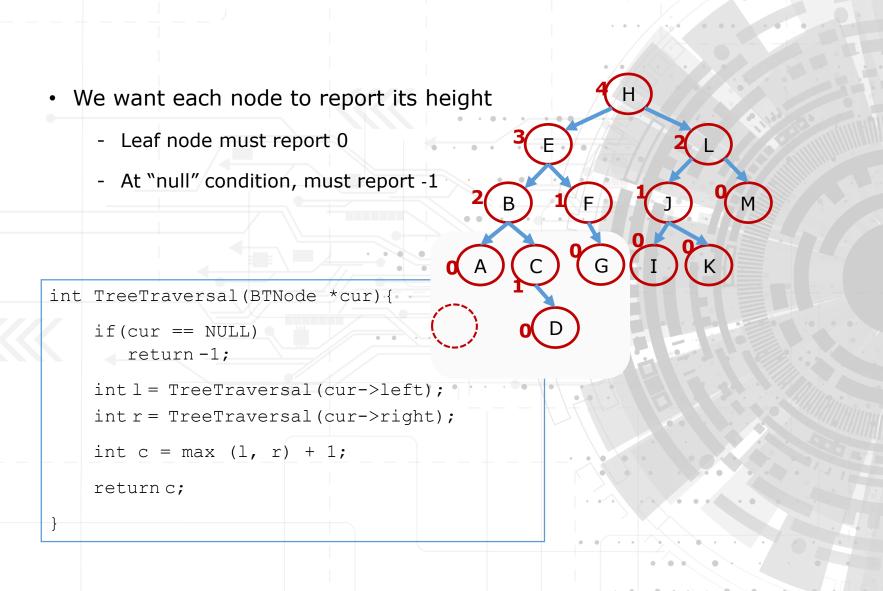

2 B 1 F J M 0 A C G I K

Does information propagate upwards or downwards?

- Height of a node = number of links from that node to the deepest leaf node
- How does each node calculate its height?
  - What is the height of node D, C, H?
- Go through entire tree:
   calculate and store height of
   each node in the item field

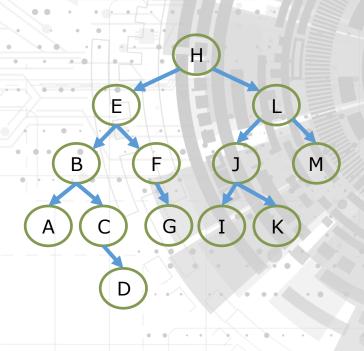

# **QUESTIONS**

- Does the tree traversal order matter?
- Depth of a node = number of links from that node to the root node. How does each node calculate its depth?

 Height of a node = number of links from that node to the deepest leaf node

```
We want each node to report its height
   - Leaf node must report 0
   - At "null" condition, must report -1
   int TreeTraversal(BTNode *cur) {
       if(cur == NULL)
          return -1;
       int l = TreeTraversal(cur->left);
       int r = TreeTraversal(cur->right);
       int c = \max(1, r) + 1;
       return c;
```

## **QUESTIONS**

- Does the tree traversal order matter?
- Height of a node = number of links from that node to the deepest leaf node
- Depth of a node = number of links from that node to the root node. How does each node calculate its depth?

```
void TreeTraversal(BTNode *cur, int d) {
   if(cur == NULL)
      return;

//print cur->item and d;

TreeTraversal(cur->left, d+1);

TreeTraversal(cur->right, d+1);

return;
}
A C G I K
```

#### **OUTLINE**

### LEVEL-BY-LEVEL: BREADTH-FIRST SEARCH

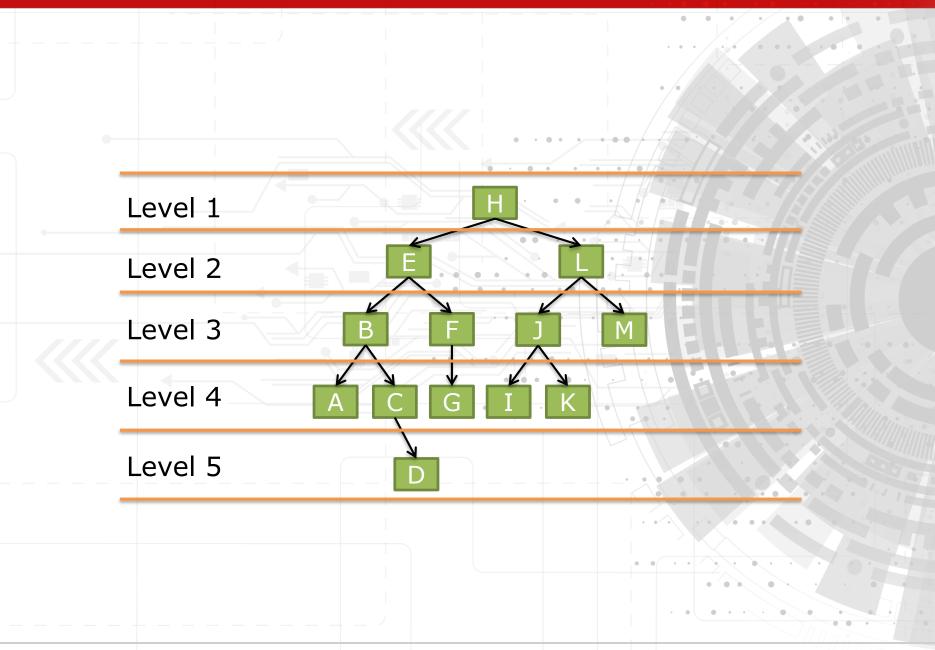

begins at the root and explores as far as possible along each branch before backtracking

E.g. the post-order traversal

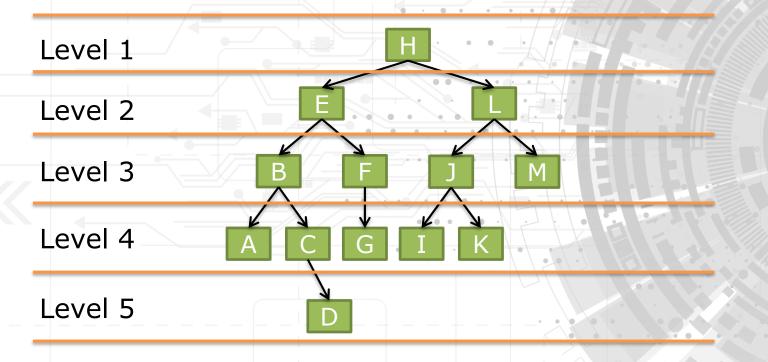

Depth-first search

begins at a root node and inspects all its children nodes. Then for each of those children nodes in turn, it inspects their children nodes, and so on.

Breadth-first search

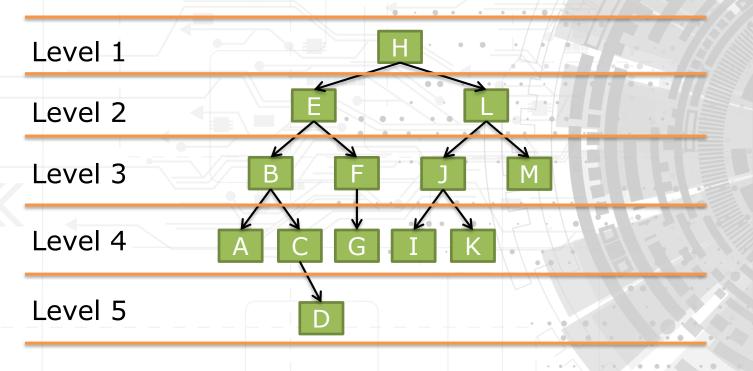

Hint: Make use of another data structure

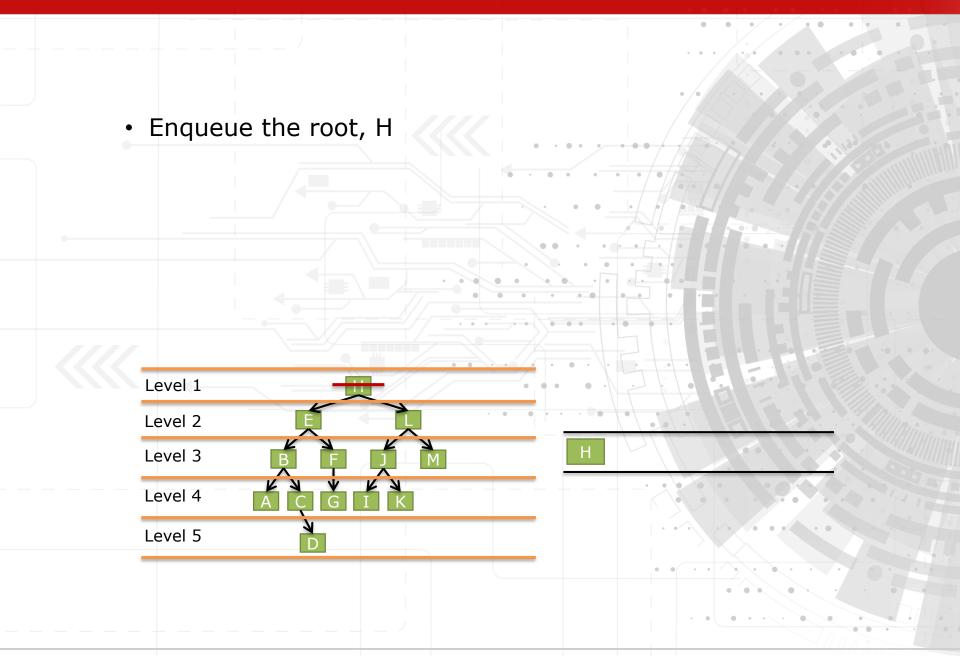

Nodes stored in order accessed in tree...

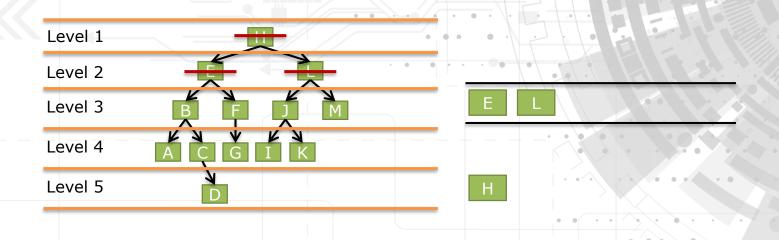

Use a queue! Root node should be first

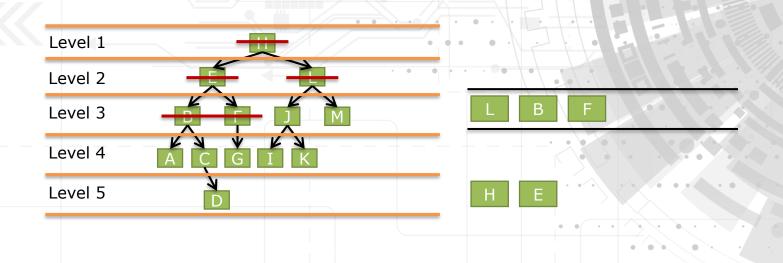

Nodes stored in order accessed in tree

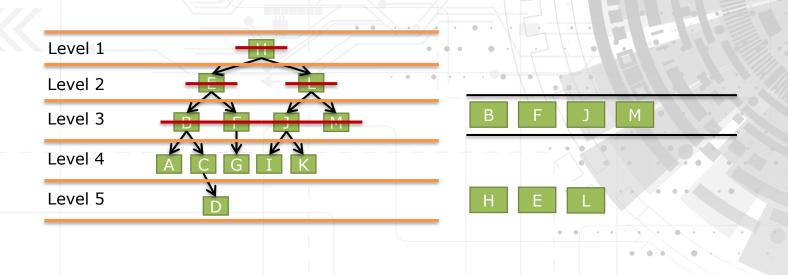

- Enqueue the root, H
- Dequeue H, and enqueue H's children

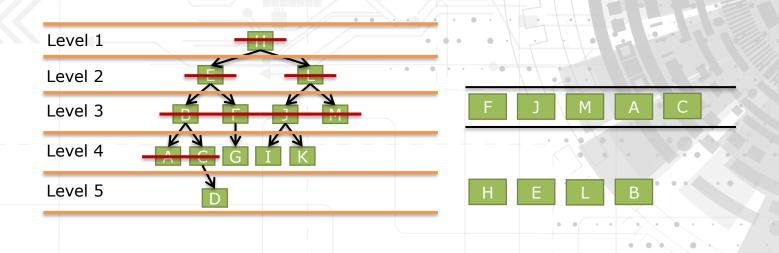

- Enqueue the root, H
- Dequeue H, and enqueue H's children
- Dequeue E, and enqueue E's children

- Enqueue the root, H
- Dequeue H, and enqueue H's children
- Dequeue E, and enqueue E's children
- Dequeue L, and enqueue L's children

- Enqueue the root, H
- Dequeue H, and enqueue H's children
- Dequeue E, and enqueue E's children
- Dequeue L, and enqueue L's children
- Dequeue B, and enqueue B's children

### YOU SHOULD BE ABLE TO

- Binary tree Traverse:
  - Pre-order
  - In-order
  - Post-order
- Write recursive binary tree functions using the TreeTraversal template as a starting point
- Based on the traversal of the binary tree, do a lot of things: print, count numbers, count height/depth, find grandchildren,..., etc.
